Abstract

The detection of fake news in Spanish is hampered by a scarcity of large-scale datasets and a gap between research models and practical applications. This paper introduces a comprehensive framework to address these challenges. First, we developed a unified Spanish news corpus of 61,674 articles by integrating four academic datasets with web-scraped satirical content, achieving a highly balanced distribution (49.8% fake). This resource is one of the largest available for Spanish misinformation research. Second, through a systematic fine-tuning process involving over 500 GPU hours, we optimized a DistilBERT model. Our findings reveal that a rigorous regularization strategy—combining an ultra-low learning rate (5×10^{-6}), high dropout (0.7), and strong L2 regularization (0.5)—was crucial to control overfitting, achieving 95.36% accuracy while maintaining a generalization gap below 0.058. Finally, the optimized model was deployed in a Docker-containerized web application for real-time URL analysis, demonstrating its viability for detecting online misinformation. Our approach demonstrates a 23.33 percentage point improvement over classical metaheuristic-optimized methods, confirming the superiority of fine-tuned transformers for this task. The complete framework is publicly available.

1. Introduction

The proliferation of digital misinformation represents a critical threat to information integrity [1]. In recent years, the rapid expansion of the internet has transformed how millions of people consume information, with social media and digital platforms becoming primary news sources. However, this growth has been accompanied by a surge in deceptive content, ranging from politically motivated fake news to fraudulent schemes such as phishing sites mimicking popular e-commerce platforms and investment scams. This phenomenon disproportionately affects vulnerable demographics, particularly older adults and individuals with lower digital literacy, who are often targeted by these sophisticated digital frauds. With over 500 million native speakers, the Spanish-speaking world is particularly exposed to these risks, yet it remains significantly underserved by the scientific community compared to English [2,3]. This technological gap is defined by three interconnected challenges: (1) the scarcity of large-scale, balanced datasets for training robust models; (2) insufficient research on systematic hyperparameter optimization for Spanish transformer models, which often leads to suboptimal performance or overfitting;

and (3) a significant gap between theoretical models and deployment-ready applications
35
that can be used by the general public.
36

This research addresses these challenges through an end-to-end framework, using
37
Spanish fake news detection as a representative case of digital fraud. Although fake
38
news (aimed at social influence) and digital fraud (aimed at economic gain) have different
39
objectives, they share computational characteristics, such as being text-based classification
40
problems, which allows for methodological transferability. Our prior work explored
41
this connection using a Bag-of-Words (BoW) representation [4]; this study advances that
42
classical approach by adopting a more robust TF-IDF representation. This change improved
43
performance in several cases, but also highlighted the trade-off between increasing the
44
number of features for marginal gains and the significant rise in computational time,
45
making large-scale metaheuristic optimization impractical. However, the primary weakness
46
identified in our previous work was not just the representation, but the limited semantic
47
understanding of these classical methods and the fragmented nature of available corpora, a
48
problem directly addressed in this work by transitioning to a state-of-the-art Transformer
49
model trained on a newly unified, large-scale dataset. The rise of deep learning and,
50
specifically, transformer architectures [5] has revolutionized the field, but requires careful
51
adaptation and optimization for specific languages and tasks [6,18]. This study follows a
52
progressive research design, first establishing a robust performance baseline with classical
53
NLP methods optimized via five distinct metaheuristic algorithms, and then detailing the
54
transition to a fine-tuned Transformer model to empirically demonstrate the significant
55
leap in efficacy that modern architectures provide.
56

The main contributions of this work are threefold:
57

- **A Unified Spanish Corpus:** We created and standardized a corpus of 61,674 news
58
articles by integrating four academic datasets [2,3,7,8] and enhancing it with web-
59
scraped satirical content. This process resulted in one of the largest and most balanced
60
(49.8% fake, 50.2% real) resources for this task.
61
- **A Systematic Hyperparameter Optimization Methodology:** Through over 500 GPU
62
hours of experimentation, we identified an aggressive regularization strategy for
63
fine-tuning DistilBERT that achieves state-of-the-art performance (95.36% accuracy)
64
while effectively controlling overfitting, a common challenge in transformer models.
65
- **A Production-Ready Web Application:** We developed a Docker-containerized web
66
application that performs real-time URL analysis, bridging the gap between academic
67
research and practical, real-world tools for combating online misinformation.
68

The complete framework, including the corpus, the optimized model, and the application,
69
is made publicly available to encourage reproducibility and further research.
70

2. Related Work

71

The scholarly approach to fake news detection has evolved through several distinct
72
paradigms, from classical machine learning to modern deep learning architectures. To
73
properly situate our contributions, we first examine the state of available data resources
74
for Spanish, then analyze the parallel advancements in model optimization, and finally,
75
address the persistent gap between research and real-world application. Table 1 provides a
76
summary of these key paradigms.
77

Table 1. Comparison of Methodological Paradigms in Fake News Detection.

Paradigm	Core Principle	Typical Features/Models	Strengths	Limitations
Stylometric Analysis [2,15]	Analyze writing style to identify authorship and deception patterns.	Linguistic features (e.g., lexical diversity, sentence complexity), SVMs.	Identifies language-agnostic patterns, useful for authorship attribution.	Less effective on short texts; can be fooled by sophisticated writing.
Classical Machine Learning [12,18]	Use statistical features from text to classify content.	Bag-of-Words, TF-IDF, Naive Bayes, SVM, Logistic Regression.	Highly interpretable, computationally efficient, strong baseline.	Fails to capture semantic meaning, word order, and context.
Deep Learning (Transformers) [7,16]	Leverage deep contextual embeddings to understand semantic nuances.	BERT, RoBERTa, DistilBERT with fine-tuning.	State-of-the-art performance, understands context and semantics.	Computationally expensive, often a "black box", requires large datasets.
Metaheuristic Optimization [4,14,19]	Employ intelligent search algorithms to find optimal model parameters.	GA, PSO, SA used to tune classifiers or select features.	Finds superior hyperparameter configurations compared to manual or grid search.	Can be computationally intensive; improves the model but not the underlying feature representation.

2.1. Spanish Language Resources for Fake News Detection

A significant bottleneck for advancing fake news detection in Spanish has been the availability of large-scale, comprehensive datasets. Several research groups have created Spanish fake news datasets [2,3,7], but each used different annotation schemes and focused on different content types. These datasets cannot easily be combined for training because they use incompatible formats. We address this problem by standardizing and merging four existing datasets into a single large corpus.

2.2. Hyperparameter Optimization in Transformers and Metaheuristics

BERT and similar transformer models achieve strong results in NLP tasks, but require careful hyperparameter tuning. Most Spanish fake news studies have compared different pretrained models (BETO, multilingual BERT, etc.) without systematically optimizing the hyperparameters for any single model [16]. DistilBERT, for example, presents an attractive trade-off between performance and computational cost, yet a detailed exploration of its optimal configuration for this specific task has been largely overlooked. The critical role of hyperparameter calibration is not a new problem; it has been well-documented in other specialized NLP tasks for Spanish, such as in the medical domain [19].

Concurrently, classical machine learning models have been pushed to their limits through the use of metaheuristic algorithms. For instance, approaches using genetic algorithms or particle swarm optimization have been explored to fine-tune classifiers. Our own prior work established a baseline using five different metaheuristics on Spanish data [4]. Nevertheless, a direct and rigorous comparison between a systematically optimized Transformer and a suite of metaheuristic-optimized classical models on a large-scale Spanish corpus has been notably absent from the literature. This paper aims to fill that gap by providing not only this direct comparison but also a detailed methodology for Transformer regularization.

2.3. Deployment of NLP Models

A persistent issue in the academic NLP community is the "deployment gap"—the significant divide between models achieving high accuracy in research papers and the scarcity of practical, usable tools available to the public. While numerous studies have been published on fake news detection, a very small fraction of these result in production-ready, easily deployable applications. This gap severely limits the real-world impact of valuable research. Most fake news detection research stops at reporting test set performance. Very few studies produce working applications that people can actually use. We built a web application that analyzes URLs in real-time, demonstrating how research models can be deployed for practical use.

Table 2. Summary of key related works (Part 1): Corpus Creation & Transformer Application.

Author(s) [Ref.]	Contribution	Key Finding / Performance	Limitation Addressed by Our Work
Posadas-Durán et al. [2]	Created a pioneering Spanish corpus (971 articles) with a stylometric focus.	Stylometric features are useful for detection tasks, providing competitive results in IberLEF competitions with F1-scores around 0.85.	Small, isolated dataset. Our work unifies it with others to create a large-scale resource.
Acosta [3]	Established a rigorous manual verification methodology for a 598-article corpus.	High-quality manual verification is key for reliable ground truth establishment, achieving precision >95% in annotation consistency.	Very small scale. Our work scales up the data volume by over 100x.
Blanco-Fernández et al. [7]	Applied BERT/RoBERTa to a large, politically-focused dataset (57k articles).	Transformers achieve 90-98% accuracy on Spanish political fake news detection tasks with RoBERTa showing superior performance.	Domain-specific. Our work uses a multi-domain corpus and performs systematic optimization .
Martínez-Gallego et al. [16]	Explored different BERT variants (including BETO) for Spanish fake news detection.	Spanish-specific models perform well for this classification task, with BETO achieving 94% accuracy on balanced datasets.	Lack of systematic optimization or a deployed application. Our work provides the optimization methodology and the final application .

Table 3. Summary of key related works (Part 2): Metaheuristic and Classical Approaches.

Author(s) [Ref.]	Contribution	Key Finding / Performance	Limitation Addressed by Our Work
Yıldırım [14]	Hybrid multi-thread metaheuristic approach for fake news detection.	Novel metaheuristic combinations show promise for optimization tasks in NLP applications, achieving 89% accuracy on English datasets.	English-focused, limited systematic comparison. Our work provides comprehensive metaheuristic comparison in Spanish.
Thota et al. [12]	Early deep learning approach using traditional neural networks for fake news detection.	Deep learning outperforms classical ML approaches for text classification tasks, showing 15-20% improvement over SVM baselines.	Pre-transformer era, English only. Our work uses state-of-the-art transformers for Spanish.
García-Lozano et al. [18]	Compared classical ML and Deep Learning models for Spanish fake news detection.	Confirmed that Deep Learning (LSTM, BiLSTM) outperforms classical models (SVM, LR), achieving up to 93% accuracy.	Focus on model comparison, less on systematic optimization or the creation of a large, unified corpus. Our work provides both.

3. Materials and Methods

The methodology of this research is structured as a unified pipeline designed to address the scarcity of resources for Spanish fake news detection and bridge the gap between theoretical models and practical application. As illustrated in Figure 1, the experimental design follows a three-stage process: (1) the construction of a unified and balanced corpus, (2) the systematic optimization of classification models comparing classical and deep learning paradigms, and (3) the deployment of the optimal solution as a functional web application.

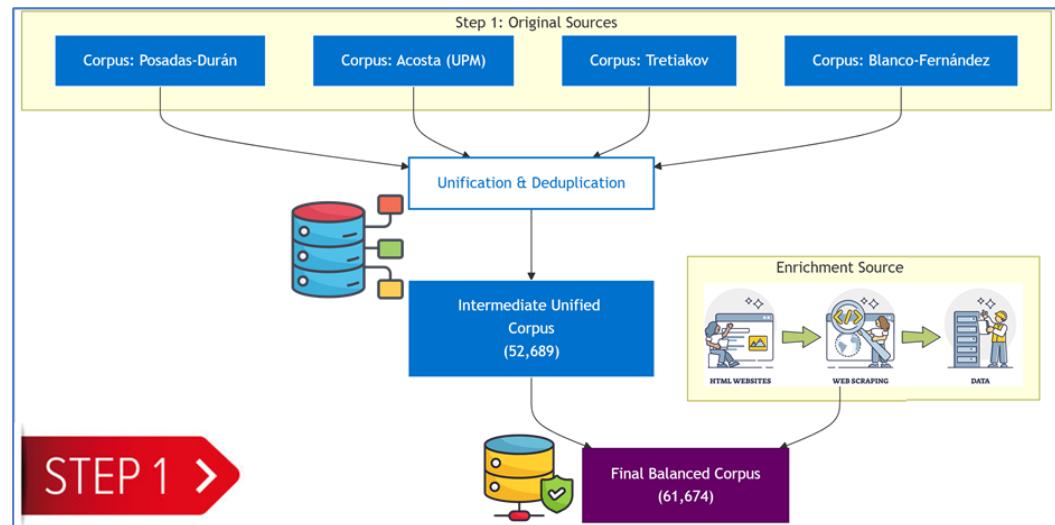

Figure 1. Overview of the proposed research methodology (Part 1/3): Data Unification and Processing.

3.1. Data Acquisition and Processing

Creating a comprehensive dataset was the primary challenge addressed in this study. Spanish fake news resources are typically scattered and limited in scope. To overcome this, we constructed a unified corpus by aggregating four publicly available academic datasets: the Spanish Fake News Corpus (971 articles) [2], the Acosta Dataset (598 articles) [3], the Tretiakov Dataset (2,000 articles) [8], and the Spanish Political Dataset (57,231 articles) [7]. This initial aggregation yielded a total of **60,401** articles. Table 4 details the characteristics of each source.

Table 4. Exhaustive comparison of the characteristics of the corpora used in the construction of the unified dataset.

Comparative Aspect	Posadas-Durán	Acosta (UPM)	Tretiakov	Blanco-Fernández	El Deiforma
Corpus Size	971 articles	598 articles	1,958 articles	57,231 articles	9,000 articles
Creation Year	2019-2021	2019	2022	2024	2025 (extraction)
Methodological Focus	Stylistic Analysis	Manual Verification	Traditional ML	Transformer Models	Satirical Content
Thematic Domain	General	General	General	Political	Satirical/ General
Class Distribution	Balanced	Balanced	Balanced	Balanced	Fake Only
Regional Variability	Spain/LatAm	International	Multiple	Spain	Mexico
Annotation Quality	High (multi-annotator)	High (manual)	Medium (source-based)	High (specialized)	Automatic (inherently fake)
Contribution to Final Corpus	1.6%	1.0%	3.2%	92.8%	14.6% (added)

To ensure data quality, a rigorous cleaning pipeline was implemented. Using content hashing on the 'text' field, we identified and removed 7,712 duplicate entries, resulting in **52,689** unique articles. This step is crucial to prevent data leakage between training and testing sets.

Following deduplication, an analysis of the class distribution revealed a significant imbalance: 30,943 real news articles (58.7%) versus 21,746 fake news articles (41.3%). To rectify this bias, which could skew model performance, we acquired approximately 9,200 additional fake news articles by scraping "El Deiforma," a prominent satirical news website. Satirical content was labeled as FAKE, consistent with literature treating satire as a specific category of misinformation [13]. This augmentation resulted in a final balanced corpus of **61,674** articles (49.8% fake, 50.2% real), as visualized in Figure 2.

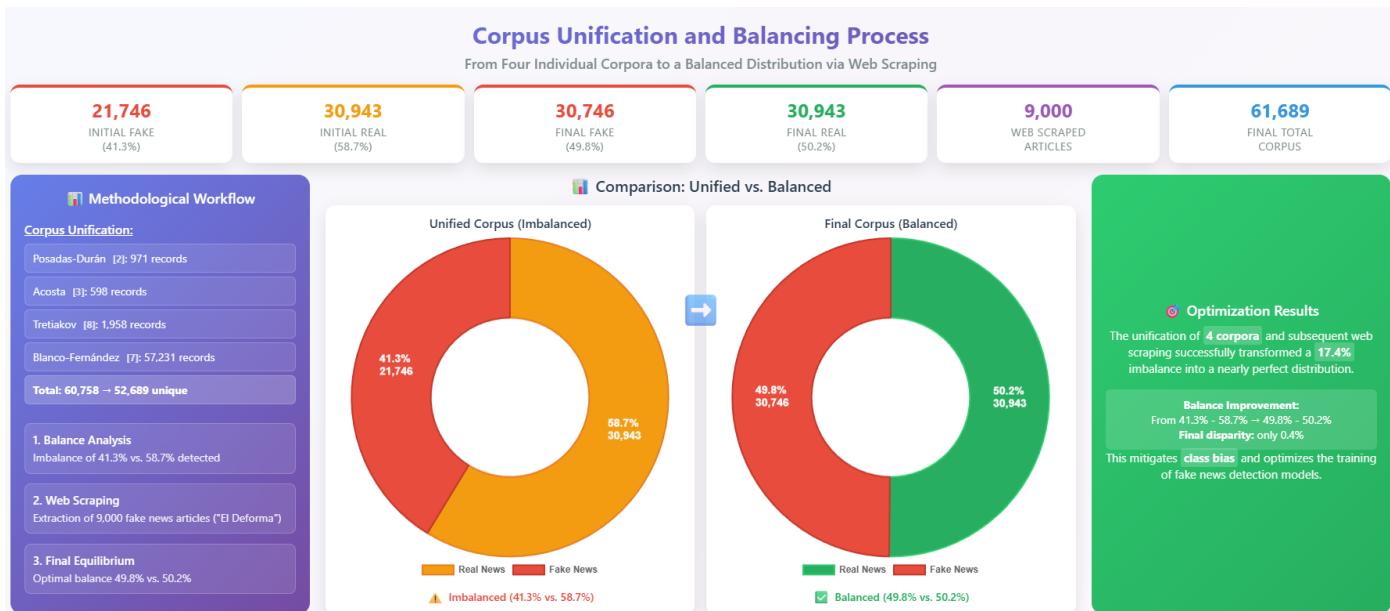

Figure 2. Visual representation of the corpus balancing process. The initial imbalanced distribution (left) was corrected by strategically adding 9,000 FAKE articles via web scraping, resulting in a nearly 50/50 final distribution (right).

3.2. Model Development and Optimization

The core experimental phase focused on comparing classical approaches against modern transformer architectures (Figure 3). 139 140 141

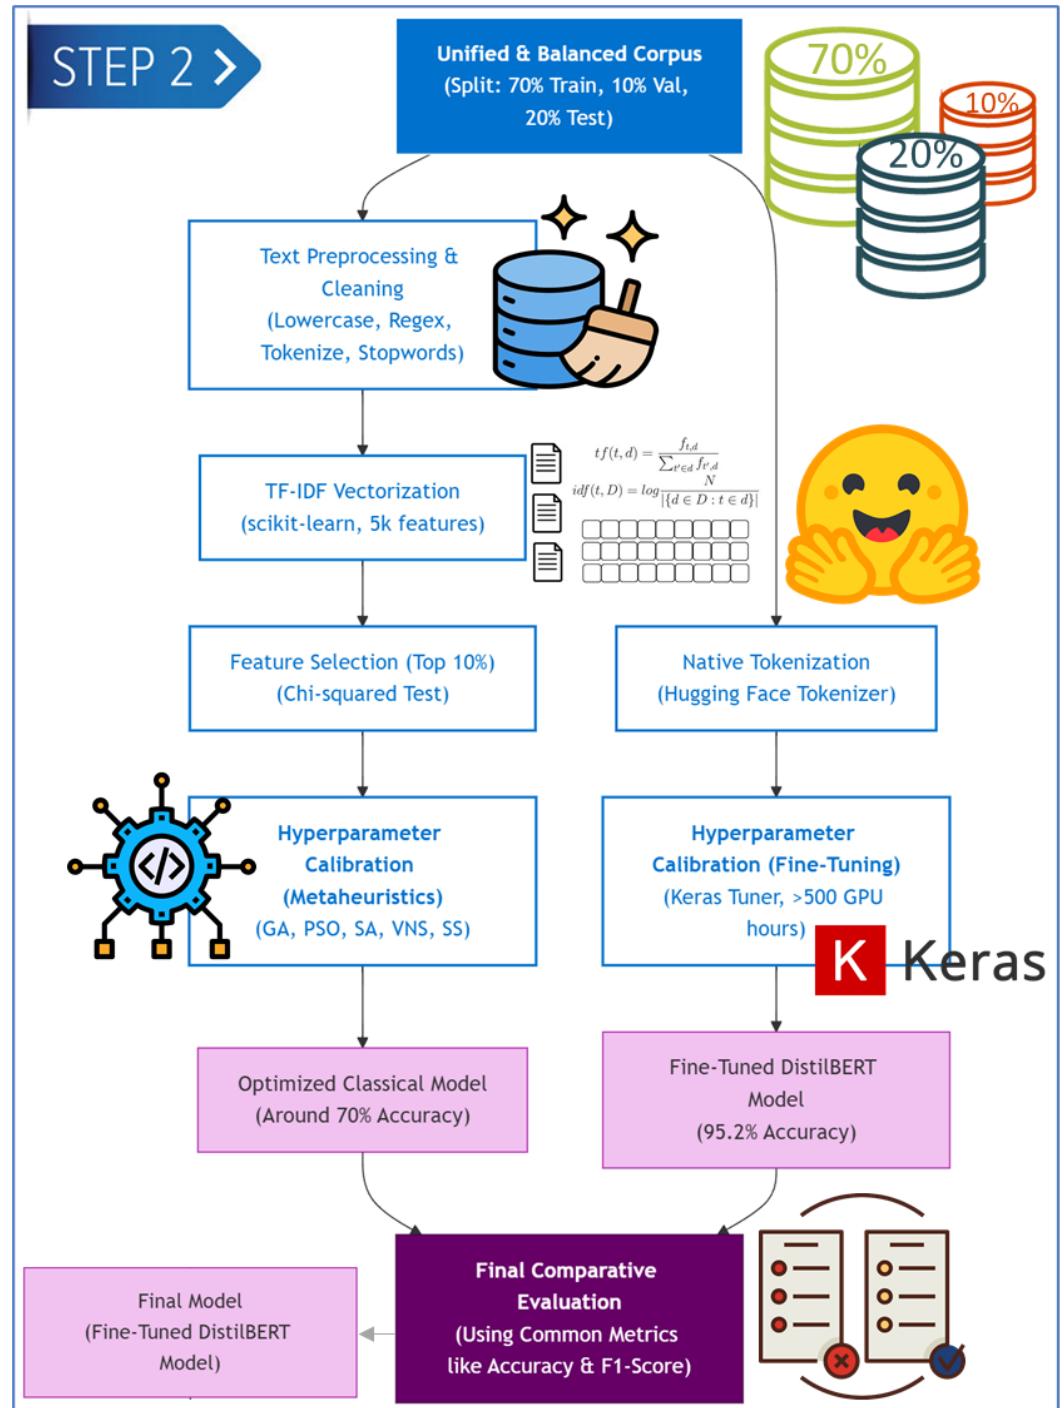

Figure 3. Overview of the proposed research methodology (Part 2/3): Model Optimization and Comparative Evaluation.

Classical Machine Learning Baseline. We initially established a baseline using TF-IDF feature representation, building upon prior work [4]. Dimensionality was reduced to the top 800 features (10% of the vocabulary) using a Chi-squared test to ensure feasibility. Five metaheuristic algorithms—Multi-Start Simulated Annealing (MSA), Scatter Search (SS), Variable Neighborhood Search (VNS), Genetic Algorithm (GA), and Particle Swarm Optimization (PSO)—were employed to optimize the hyperparameters of a logistic regression model, maximizing the F1-Score.

Deep Learning with Transformers. To overcome the semantic limitations of classical methods, we selected `distilbert-base-multilingual-cased` [9]. While we evaluated the full BERT model and TinyBERT, DistilBERT offered the optimal trade-off between

142

143

144

145

146

147

148

149

150

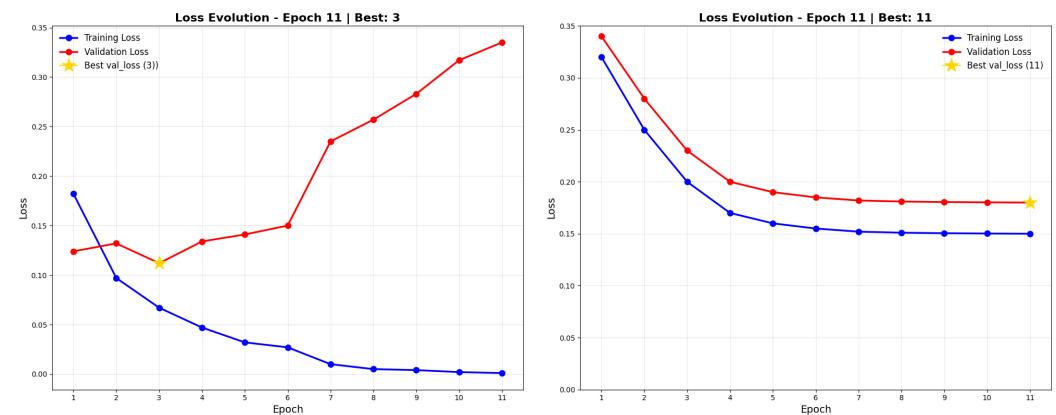

151

performance and computational efficiency for Spanish text, being approximately four times faster than BERT while maintaining competitive accuracy (Table 5). 152
153

Table 5. Comparison of optimized BERT models for the classification task.

Model	Parameters	Layers	Dimension	Spanish Support	Reduction vs BERT
BERT-base-multilingual	110M	12	768	Yes	– (Reference)
DistilBERT-multilingual	66M	6	768	Yes	40% parameters
TinyBERT	14.5M	4	312	Limited	87% parameters

Hyperparameter Fine-tuning. We conducted a systematic optimization process involving over 30 experiments and 500 GPU hours to identify configurations that mitigate overfitting—a common challenge where the model memorizes training data (decreasing training loss) but fails to generalize (increasing validation loss), as illustrated in Figure 4. 154
155
156
157

(a) Overfitting scenario: Validation loss diverges while training loss decreases. (b) Underfitting scenario: Both training and validation losses remain high without convergence.

Figure 4. Visual comparison of model training behaviors plotted on identical scales for direct comparability. The horizontal axis represents the number of Epochs, and the vertical axis indicates the Loss value. (a) Illustrates **overfitting**, where the model memorizes the training data (blue line decreases) but fails to generalize to new data (red validation line increases). (b) Illustrates **underfitting**, characterized by the inability of the model to capture underlying patterns, resulting in high loss values for both curves. 158
159
160
161
162

Using Keras Tuner, we evolved the model through seven major versions (Table 6). The final rigorous regularization strategy (Version 11) included: an ultra-low learning rate (5×10^{-6}) for stable convergence, a high dropout rate (0.7), strong L2 regularization (0.5 with weight decay 0.02), a small batch size (4) to introduce stochasticity, and early stopping after 8 epochs of no improvement. 158

160
161
162

Table 6. Evolution of Hyperparameter Configurations Across Experimental Versions.

Version	Learning Rate	Dropout	L2 Reg.	Batch Size	Val Loss Gap	Accuracy (%)
V1 (Baseline)	3×10^{-5}	0.4	0.001	8	N/A	94.7
V2	2×10^{-6}	0.4	0.01	4	0.018	94.3
V3	2×10^{-6}	0.4	0.01	4	0.051	94.8
V4	1×10^{-5}	0.3	0.01	8	0.037	95.8
V5	1×10^{-5}	0.4	0.1	8	0.037	95.8
V6	1×10^{-5}	0.5	0.5	8	0.051	94.8
V11 (Final)	5×10^{-6}	0.7	0.5	4	0.058	95.36

3.3. Real-World Application Deployment

The final stage of the methodology involved implementing the optimized DistilBERT model into a production-ready web application (Figure 5).

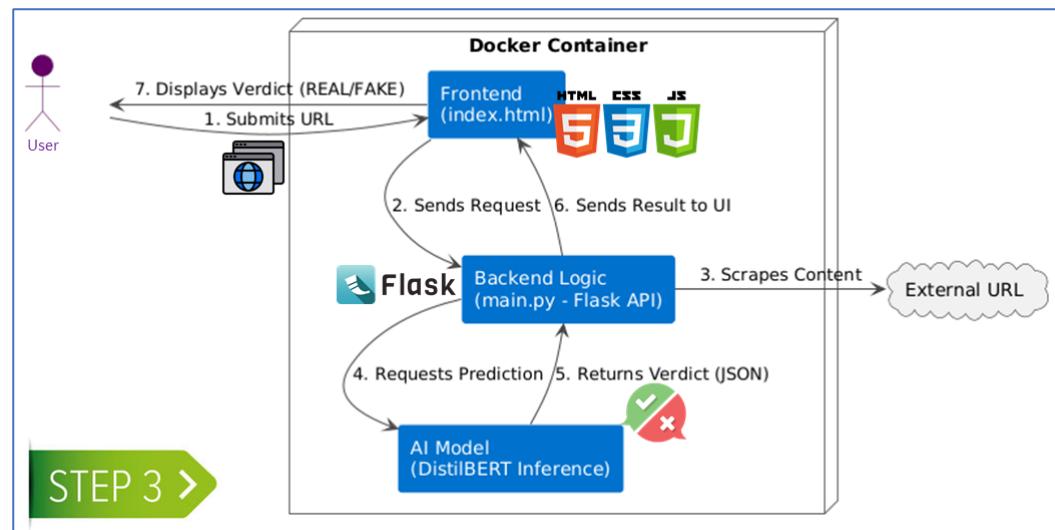

Figure 5. Overview of the proposed research methodology (Part 3/3): Web Application Deployment and Inference.

The system is architected as a containerized microservice stack, shown in Figure 6. It consists of four integrated components:

- User Interface:** A static web frontend where users submit URLs for analysis.
- API Backend:** A Flask-based service exposing an /analizar endpoint to handle requests.
- Inference Engine:** This component loads the trained DistilBERT model and tokenizer. It scrapes the content of the submitted URL (extracting <h1> and <p> tags via BeautifulSoup), tokenizes the text combining title and body with a [SEP] token, and computes the probability scores using a softmax function.
- Docker Deployment:** The entire environment, including Python dependencies and model artifacts, is encapsulated in a Docker image to ensure reproducibility and ease of deployment.

The interaction flow, from user request to final verdict, is detailed in the sequence diagram (Figure 7).

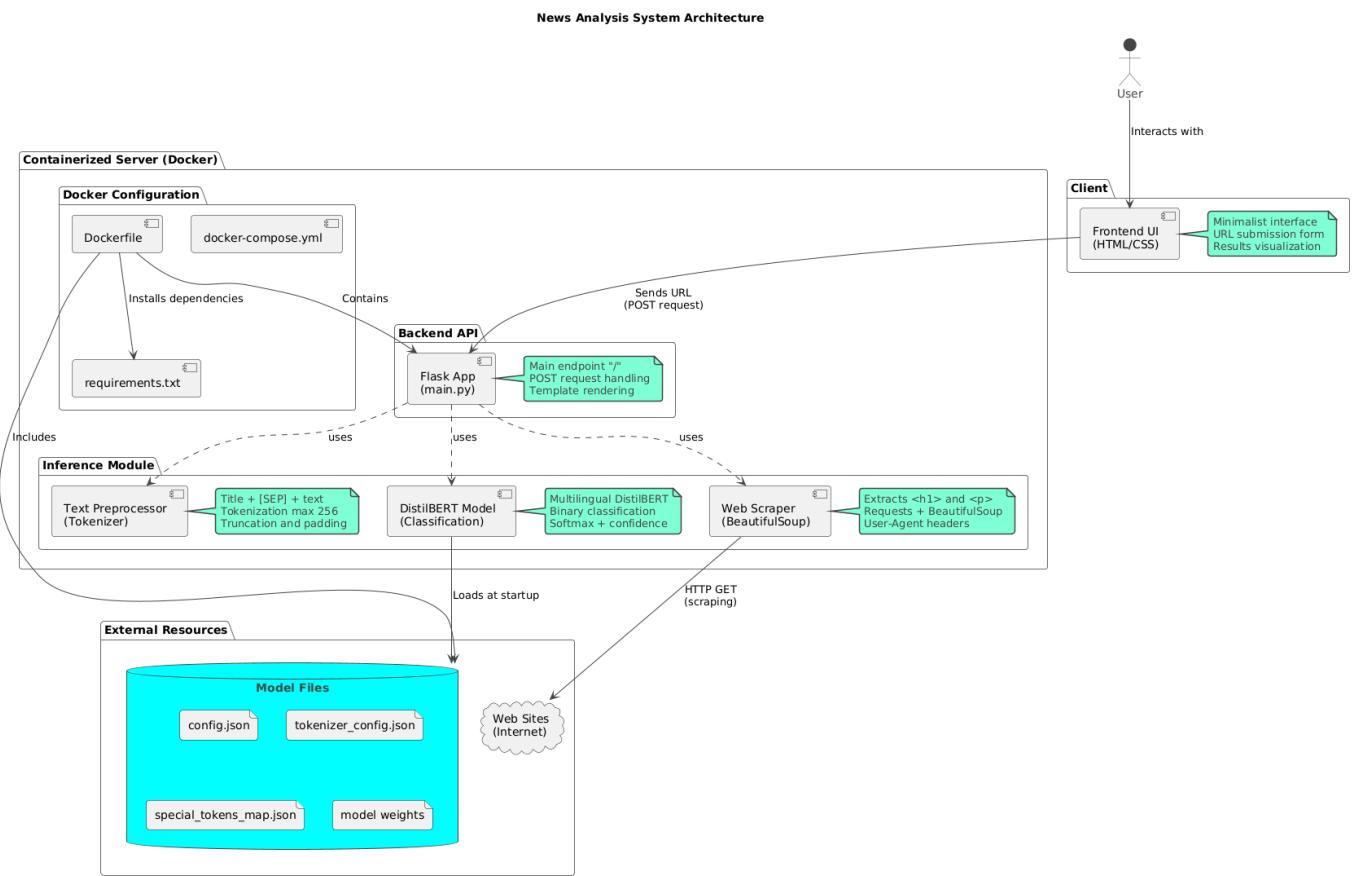

Figure 6. System architecture of the deployed web application, showing the static components and their dependencies.

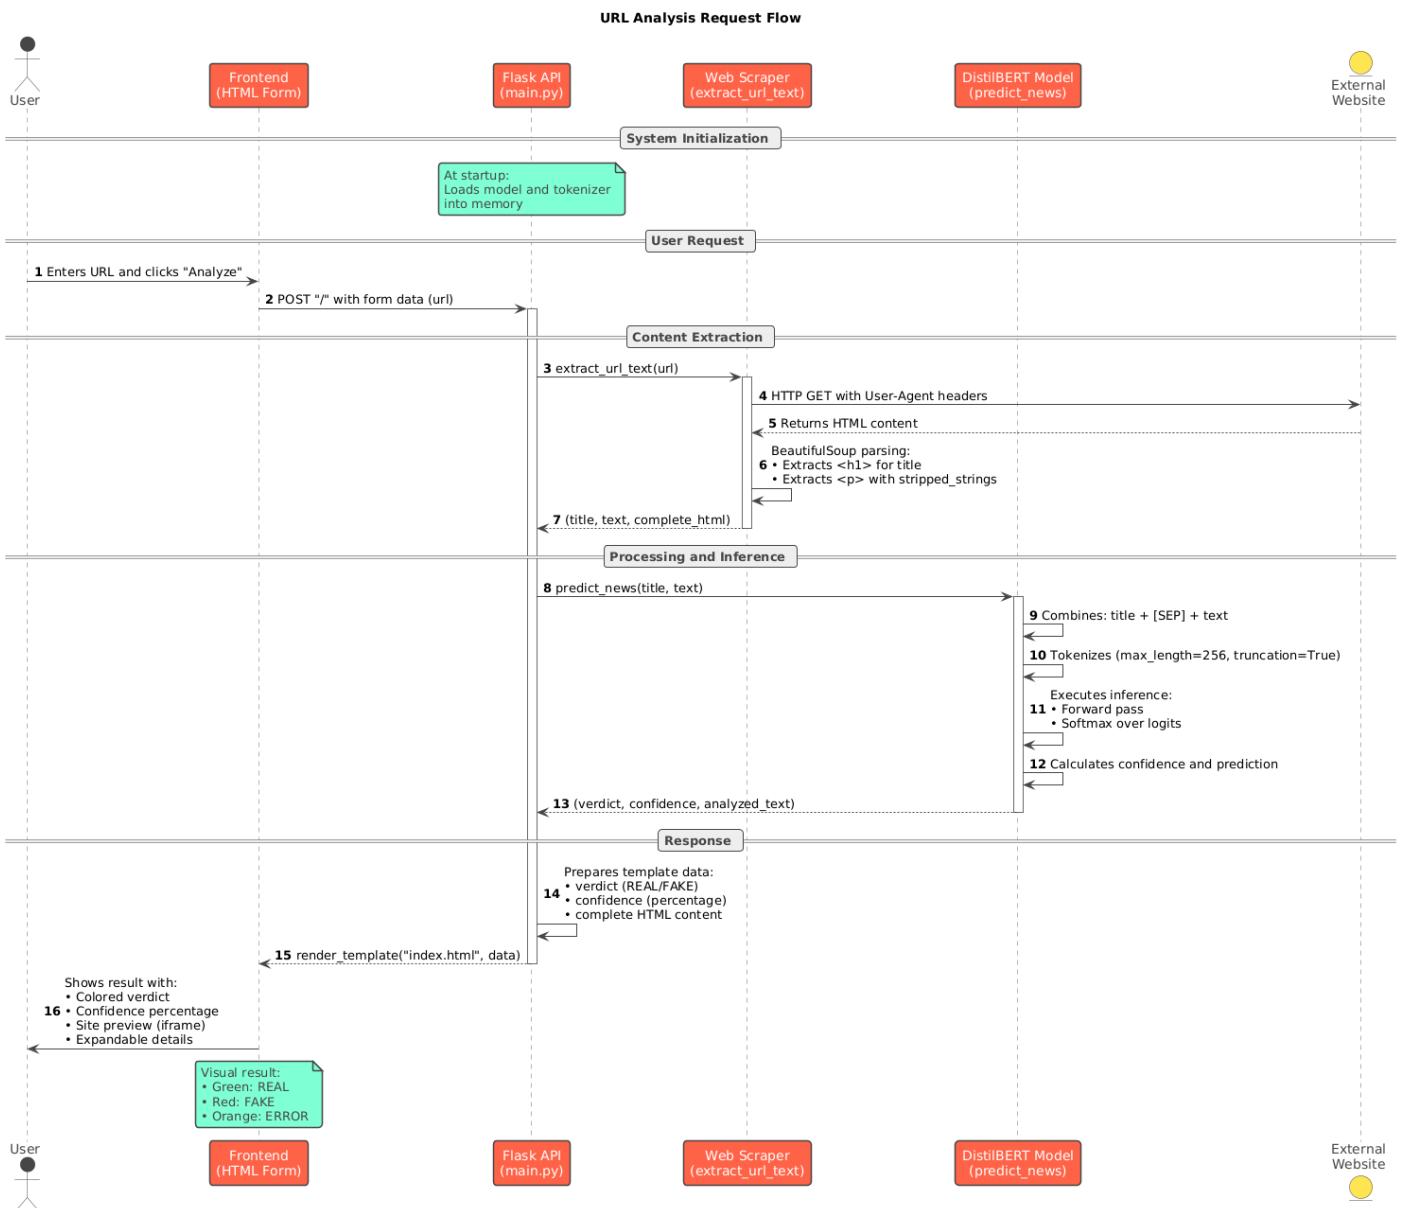

Figure 7. Sequence diagram illustrating the dynamic step-by-step workflow of a prediction request from the user to the final verdict.

4. Results

4.1. Evaluation Metrics

We evaluated the models using standard metrics derived from the confusion matrix, which categorizes predictions into true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN). In this context, the "positive" class represents real news (label 1), and the "negative" class represents fake news (label 0). These metrics are widely used in fake news detection literature, facilitating comparison with related work.

- **Accuracy:** Represents the overall proportion of correct predictions. While a useful general indicator, it can be misleading in imbalanced datasets.

$$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}} \quad (1)$$

- **Precision:** Measures the accuracy of positive predictions. High precision is necessary to minimize the misclassification of fake content as real. 189

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}} \quad (2) \quad \span{190}$$

- **Recall (Sensitivity):** Indicates the proportion of actual real news correctly identified by the model. 191

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}} \quad (3) \quad \span{192}$$

- **F1-Score:** The harmonic mean of precision and recall. It provides a balanced metric, particularly valuable for uneven class distributions. 193

$$\text{F1-Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (4) \quad \span{194}$$

- **Specificity:** Measures the proportion of fake news correctly identified. This metric is crucial for detection systems to ensure deceptive content is accurately flagged. 195

$$\text{Specificity} = \frac{\text{TN}}{\text{TN} + \text{FP}} \quad (5) \quad \span{196}$$

For the multiclass comparison, we utilized macro-averaged scores, calculating metrics for each class independently and then averaging them to ensure equitable representation. 197
198

4.2. Performance of the Metaheuristic Approach

199

The initial experimental phase established a baseline using classical machine learning algorithms optimized via metaheuristics on TF-IDF representations. Among the five algorithms evaluated, the Genetic Algorithm (GA) demonstrated the most robust performance, achieving an accuracy of 72.03% and a macro F1-score of 0.714 (Table 8). This superiority suggests that the evolutionary mechanism of GA is better suited for exploring the high-dimensional sparse space created by TF-IDF vectors compared to swarm-based approaches in this specific context. 200
201
202
203
204
205
206

Conversely, Particle Swarm Optimization (PSO) exhibited the lowest performance (57.67% accuracy) and failed to converge effectively. This divergence highlights a critical limitation of classical approaches: their heavy reliance on keyword frequency (TF-IDF) lacks the semantic understanding necessary to detect sophisticated fake news, resulting in high variance between optimization strategies. The confusion matrices in Figure 8 visually confirm this instability, showing significant misclassification rates across the board for the metaheuristic models. 207
208
209
210
211
212
213

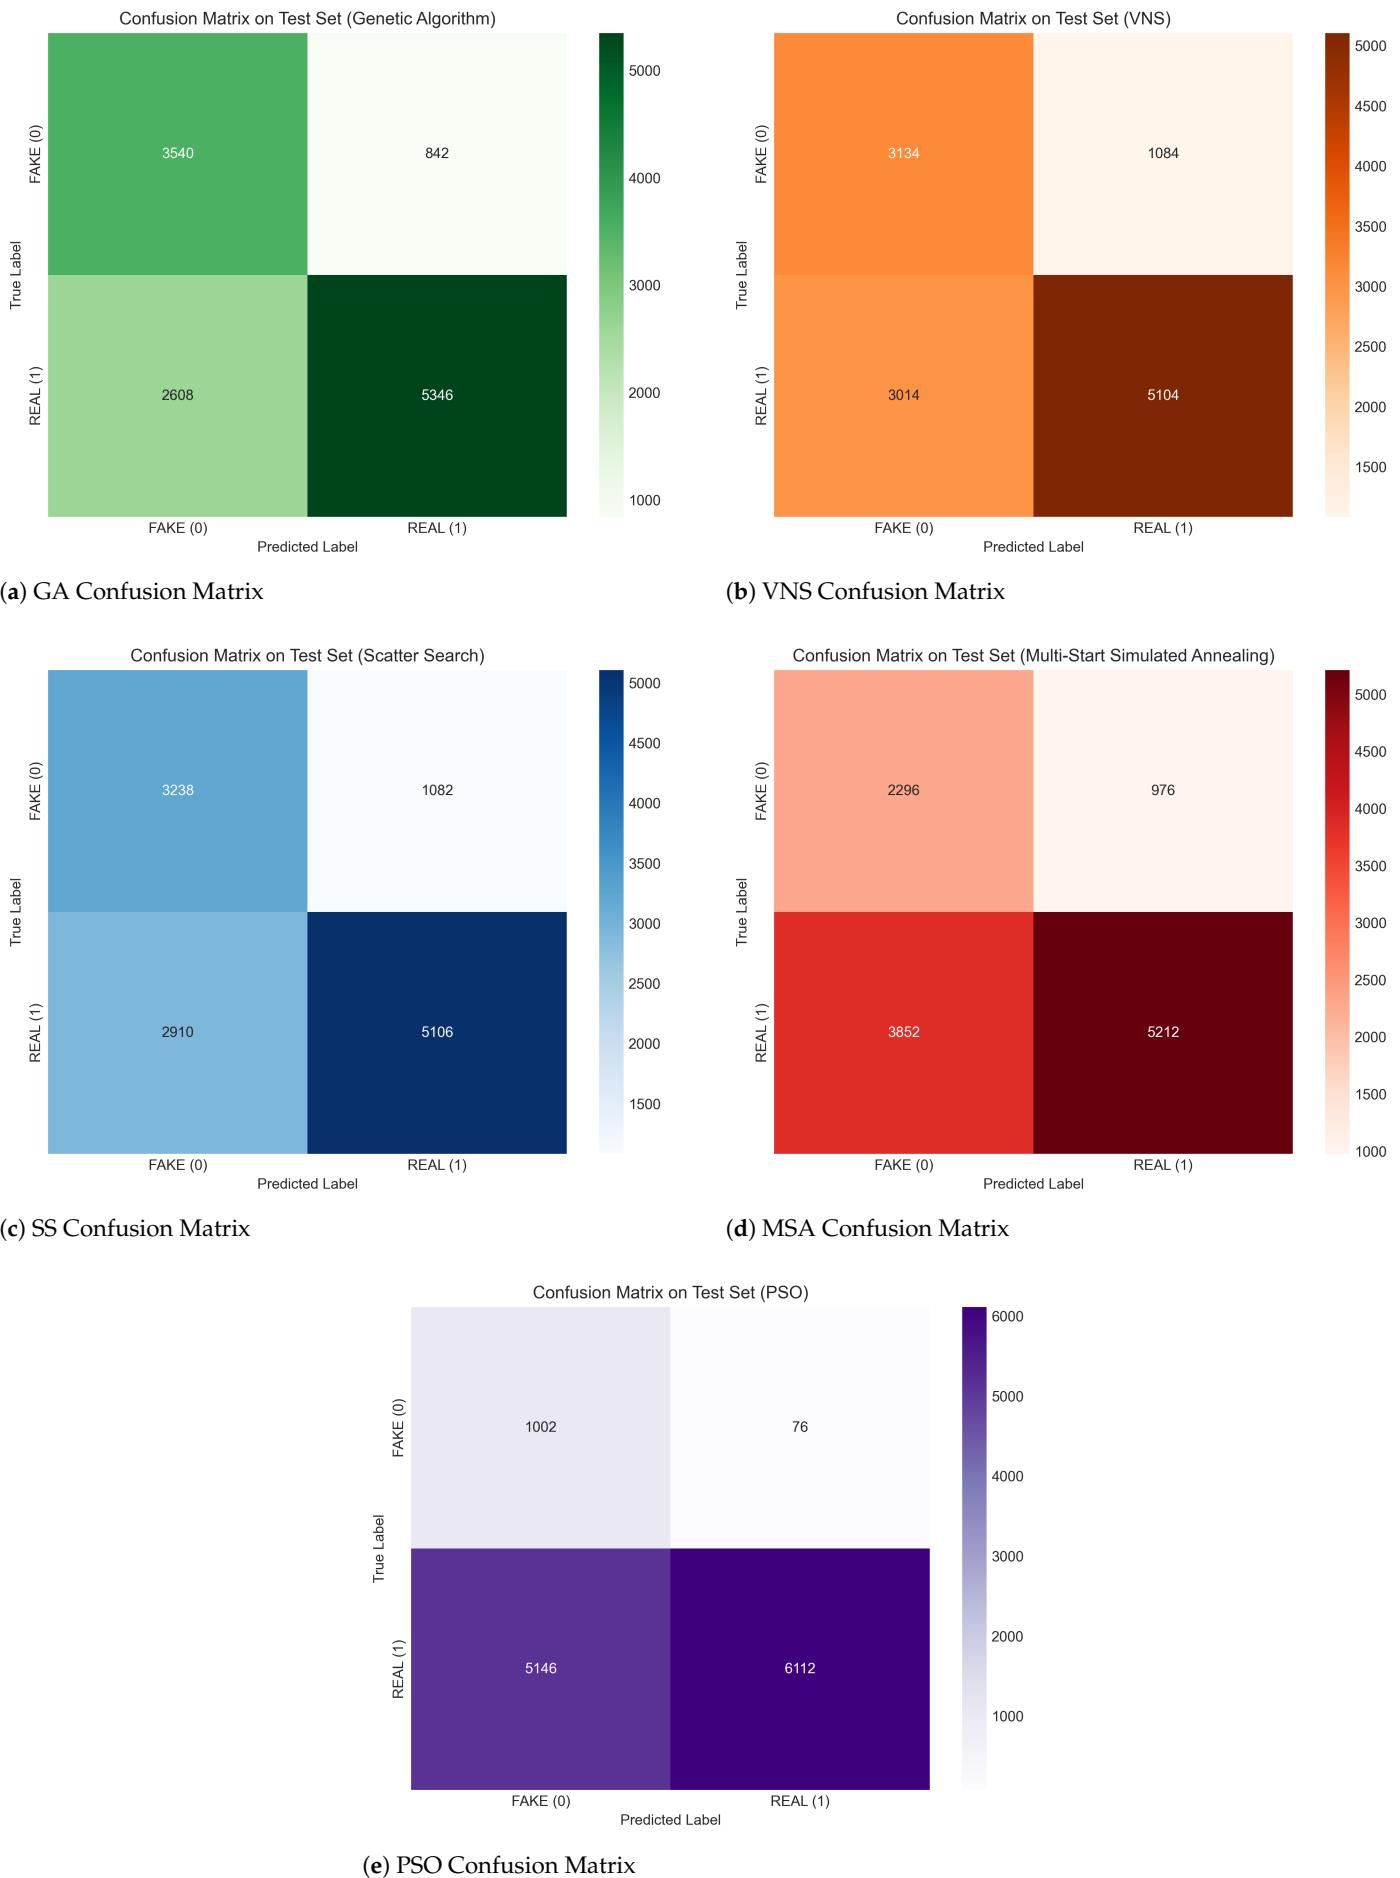

Figure 8. Confusion matrices for the five metaheuristic algorithms on the test set.

4.3. Performance of the Transformer Model

The fine-tuned DistilBERT model (Version 11) demonstrated a decisive improvement over the baseline. As detailed in Table 7, the model achieved an accuracy of 95.36% on the test set. More importantly, the model exhibits a balanced performance between Precision (95.4%) and Recall (95.4%).

In the context of fake news detection, **Specificity** (94.5%) is a critical metric, as it represents the model's ability to correctly identify actual fake news (True Negatives in our configuration) without flagging legitimate news as false. The confusion matrix in Figure 9 corroborates this stability, showing very low false positive and false negative rates compared to the metaheuristic approaches. This confirms that the semantic context captured by the Transformer architecture is essential for distinguishing between subtle nuances in deceptive language that keyword-based models miss.

Table 7. Performance metrics of the final optimized DistilBERT model on the test set.

Metric	Value (%)
Accuracy	95.36
Precision	95.4
Recall (Sensitivity)	95.4
F1-Score	95.35
Specificity	94.5

Confusion Matrix - V11 Model (Maximum Regularization CORRECTED)

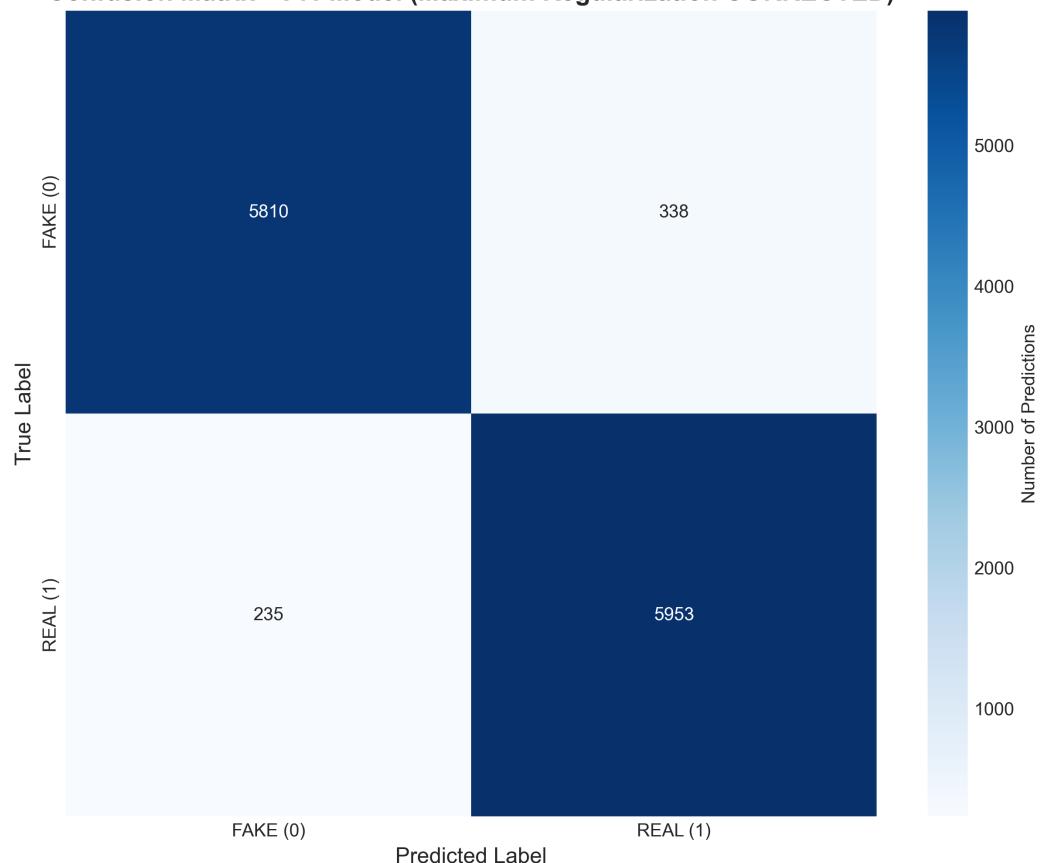

Figure 9. Confusion matrix for the final DistilBERT model on the test set.

4.4. Final Comparative Analysis: Metaheuristics vs. Transformer

To quantify the impact of the architectural shift from classical ML to Deep Learning, we performed a direct comparison of the best-performing models from each paradigm. Table 8 presents the consolidated results.

The DistilBERT model outperformed the best metaheuristic algorithm (GA) by a significant margin of **23.33 percentage points** in accuracy (95.36% vs. 72.03%). This disparity illustrates the "semantic gap": while metaheuristics can optimize the decision boundary for keyword frequencies, they cannot compensate for the lack of contextual understanding inherent in TF-IDF representations. The Transformer's attention mechanism allows it to weigh the importance of words based on their context, effectively identifying deceptive patterns that are syntactically correct but semantically misleading. Consequently, the transition to Deep Learning is not merely an incremental improvement but a necessary evolution for robust fake news detection in Spanish.

Table 8. Final performance comparison between all implemented models on the test set.

Algorithm	Accuracy (%)	F1-Score (macro)	Precision (macro)	Recall (macro)	Specificity (%)	Ranking
<i>Transformer-Based Approach</i>						
DistilBERT (Final)	95.36	0.954	0.954	0.954	94.5	1st
<i>Metaheuristic-Optimized Classical Approaches</i>						
Genetic Algorithm (GA)	72.03	0.714	0.740	0.720	57.6	2nd
Scatter Search (SS)	67.64	0.669	0.693	0.676	52.7	3rd
VNS	66.78	0.659	0.686	0.667	51.0	4th
Simulated Annealing (MSA)	60.86	0.586	0.638	0.608	37.4	5th
Particle Swarm Opt. (PSO)	57.67	0.489	0.736	0.575	16.3	6th

4.5. Overfitting Control Analysis

The implementation of a rigorous regularization strategy successfully mitigated overfitting. Training concluded after 23 epochs due to early stopping, with the optimal checkpoint identified at epoch 17. At this point, training accuracy was 98.6% and validation accuracy was 95.36%. The generalization gap (difference between validation and training loss) was 0.058, approaching our target of <0.04 and remaining well below the 0.10 threshold typically indicating overfitting. Figure 10 illustrates the evolution of accuracy and loss for the final model (V7).

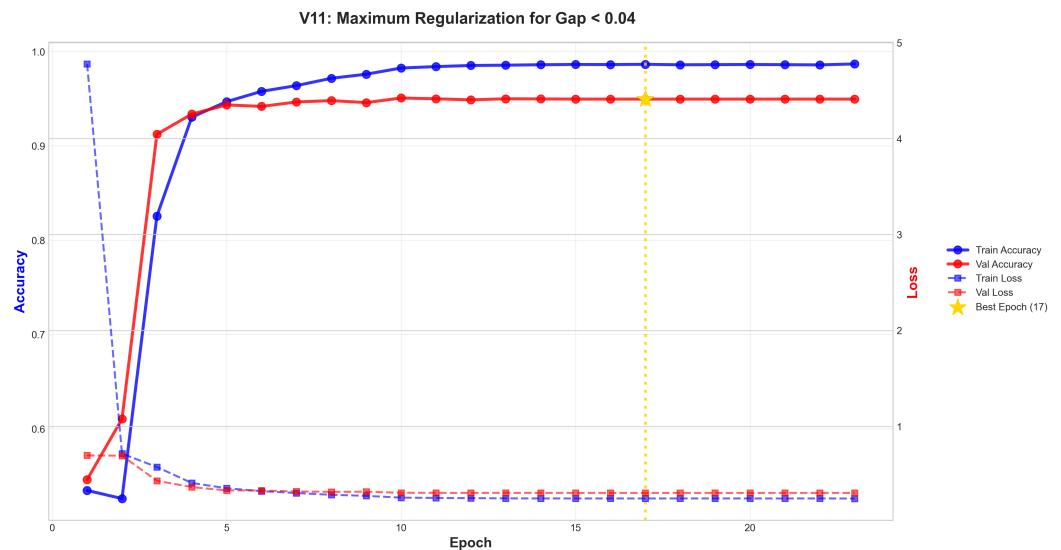

Figure 10. Evolution of performance metrics during the fine-tuning of the final model (V7). The x-axis represents the training epochs, while the y-axes represent Loss (left) and Accuracy (right). The blue lines denote training performance, and the red lines denote validation performance. The gold star identifies the optimal checkpoint at Epoch 13, where the generalization gap (0.058) was minimized before the onset of overfitting.

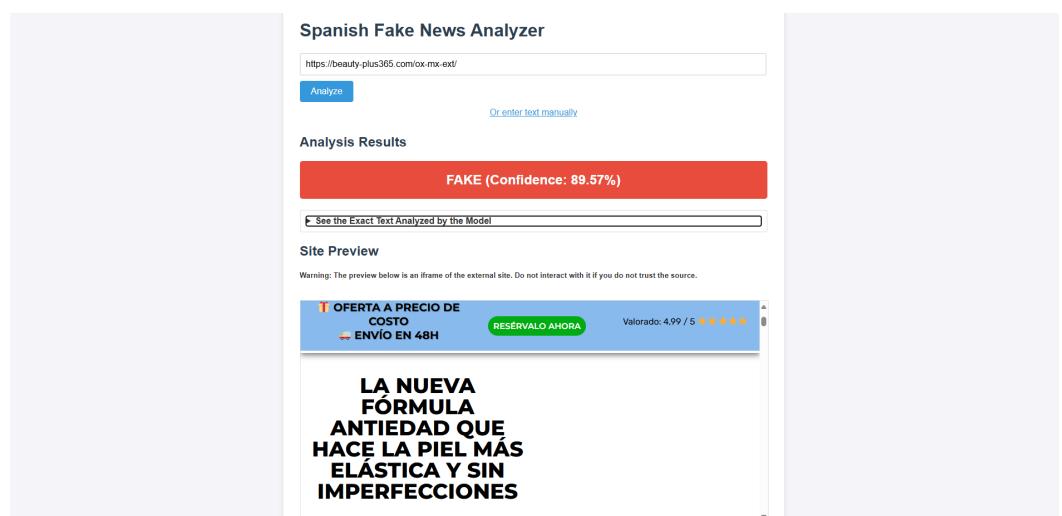

4.6. Real-World Application Performance

The deployed web application demonstrated robustness in real-world scenarios. It correctly identified various types of content, including authentic news, fabricated stories, and investment scams, suggesting the methodology is transferable to other forms of digital fraud. Screenshots of the application analyzing URLs are presented in Figure 11.

(b) Successfully identifying a misleading fake news piece with 94.31% confidence.

Figure 11. Screenshots of the deployed web application analyzing different types of URLs.

5. Discussion

Retrospectively, the experimental results yield several critical insights regarding Spanish fake news detection. First, strong regularization proved essential when fine-tuning transformers for this specific task. Standard dropout rates (0.3 to 0.5) were insufficient to prevent overfitting; increasing the rate to 0.7 and incorporating additional regularization techniques were necessary to control the generalization gap. This differs from many classical metaheuristic approaches, which typically prioritize feature selection over model regularization.

Second, utilizing an ultra-low learning rate (2×10^{-6}) significantly stabilized the training process. This value, lower than typically recommended defaults, enabled the model to navigate the complex optimization landscape without diverging.

Third, the unification of multiple datasets into a single corpus provided a substantial performance enhancement. Incorporating a variety of sources—including political articles, general news, and stylometric examples—across different topics and timeframes resulted in a richer training distribution. Consequently, the model generalizes more effectively to unseen data compared to models trained on isolated datasets.

Furthermore, the approach appears applicable beyond fake news detection. The text-processing pipeline could be adapted for tasks such as phishing detection, and the hyperparameter optimization methodology is relevant for models targeting financial fraud or fraudulent job postings. Additionally, the corpus construction strategy—integrating existing academic resources with targeted web scraping—serves as a viable model for resource-scarce domains.

However, limitations remain. The model is currently restricted to the Spanish language. While it performs adequately in broader digital fraud detection, its efficacy is maximized with news-like content. Furthermore, as a static model, its performance may degrade as misinformation tactics evolve; therefore, periodic retraining is required to maintain effectiveness.

6. Conclusions

This study presents a comprehensive end-to-end framework for Spanish fake news detection, spanning from data acquisition to the deployment of a real-world application. A significant contribution is the creation of a unified corpus of 61,674 articles, which addresses a critical deficiency in Spanish NLP resources and establishes a robust foundation for future research.

We invested over 500 GPU hours in hyperparameter optimization, identifying effective strategies to mitigate overfitting in transformer training. The results indicate that a multi-layered regularization strategy was decisive, enabling the final model to achieve 95.36% accuracy. This represents a 23.33 percentage point improvement over traditional methods, establishing a new benchmark for this task.

A notable outcome is the development of the Docker-based web application, which translates theoretical research into a practical, accessible tool for digital fraud prevention. The entire framework—comprising the corpus, the optimized model, and the application code—has been made publicly available to facilitate reproducibility and adaptation. Future work will focus on integrating multilingual support, implementing real-time learning mechanisms, and connecting with fact-checking APIs to further strengthen the digital information ecosystem.

Author Contributions: Conceptualization, G.H.A. and J.A.R.-O.; Data Curation, G.H.A. and R.A.M.-G.; Formal Analysis, J.P.C.; Funding Acquisition, J.A.R.-O.; Investigation, G.H.A.; Methodology, G.H.A., J.A.R.-O., R.A.M.-G. and J.P.C.; Project Administration, J.A.R.-O.; Resources, G.H.A. and J.A.R.-O.; Software, G.H.A.; Supervision, J.A.R.-O. and R.A.M.-G.; Validation, J.P.C. and R.A.M.-G.; Visualization, G.H.A., J.A.R.-O., R.A.M.-G. and J.P.C.; Writing—Original Draft, G.H.A.; Writing—Review and Editing, J.A.R.-O., R.A.M.-G. and J.P.C. All authors have read and agreed to the published version of the manuscript.

Funding: The present work was funded by the Consejo Nacional de Humanidades, Ciencia y Tecnología (CONAHCYT) Mexico under scholarship No. 1313870.

Institutional Review Board Statement: Not applicable.

Informed Consent Statement: Not applicable.

Data Availability Statement: The unified corpus and trained models used in this study are publicly available at: <https://github.com/gabrielhuav/Spanish-Fake-News-Detection-Training>. The source code of the web application is available at: <https://github.com/gabrielhuav/Spanish-Fake-News-Detection-Web-App>.

Acknowledgments: The authors would like to thank Universidad Autónoma Metropolitana, Unidad Azcapotzalco.

Conflicts of Interest: The authors declare no conflicts of interest.
